Abstract

This case describes a 32-year-old male with 2 months of headache accompanied with slight right-hand hemiparesis. During a physical examination, he was also detected left facial hypoesthesia. An enhanced magnetic resonance imaging (MRI) showed a large size lesion on the region of the left cerebellopontine angle, with large displacement of the brainstem and cerebellum. The tumor extended to the cavum of Meckel, displacing and pushing the left cavernous sinus upward. After analyzing the anatomical characteristics of the tumor, surgery was decided in two steps. Since the symptoms were mostly produced by the tumor part located in the posterior fossa, a decision was made to first resect that part of the tumor. With the patient in a semisitting position, we performed a left retrosigmoid craniotomy, exposing the transverse and sigmoid sinus edges. Using microsurgical technique, and ultrasonic aspirator, the complete removal of the lesion located in the posterior fossa was achieved. The patient presented a very good postoperative period, without a new neurological deficit. A month after the surgery, the patient no longer suffered from headaches or hemiparesis, but continued the left facial hypoesthesia. The pathology reported clear cell meningioma. Another month later, a transzygomatic approach plus peeling of the cavernous sinus was performed with the patient in the supine position and head rotated to the right side. Spinal drainage was previously placed. The total resection of the tumor was achieved without any surgical complication. The patient presented an excellent postoperative condition without new neurological deficit. The pathologist confirmed the diagnosis of clear cell meningioma.
